Introduction

The Unidot macro-assembler and linker was used in the 1980s (and beyond) to assemble assembly-language files for different microprocessors (i.e. Intel 8080, Zilog Z80, etc.)

Preface

The original Unidot documentation has been lost to time. This document does not pretend to be anything like the original. Rather, it has been created by reviewing the source code and some assembly-language source files that used the assembler and linker for the build toolchain. The goal is to provide a brief reference for the assembler and linker to aid in its continued use.

UASM

UASM is the generic, base, of the macro-assembler. The macro-assembler is provided as microprocessor-specific versions that are configured for the particular processor's assembly language.

In practice, a specific variant of the assembler will be used, for example **uas_{z80}** for the Zilog Z80 microprocessor.

Command Line Options

The command line supports a number of options. (Examples from Windows).^[1]

^[1] Screenshots are from the Windows platform. The interface looks similar on Mac and Linux platforms.

Directives

Within an assembly source file, **directives** are used to control aspects of the build process.

ULINK

Command Line Options

The command line supports a number of options.

Directives

Within an assembly source file, **directives** are used to control aspects of the build process.
